Loki

Motivation

- We need usable, reliable, abundant, affordable computing power

- Supercomputer vendors are going bankrupt, selling out, or giving up. (Cray Research, Cray Computer, Intel SSD, Convex, Thinking Machines)

- The success of supercomputing centers and the Internet means the amount of computing available to each individual research group has actually declined over the past few years.

- Good software is incredibly expensive to develop. We can't afford to pay for useless software hidden in the hardware price. I consider things like HPF and parallel debuggers with a graphical user interface to be useless.

- The rate of change in computing is beyond the ability of big organizations to keep pace with.

Enabling Technologies

How is it possible that one or two people can design and build a computer in a few weeks that is superior to machines which have tens of millions of dollars in research and development behind them?

- Linux - Hardware independent operating system

- PCI - Hardware independent bus

- Dramatic increase in microprocessor performance (Moore's Law).   The latest personal computer microprocessor (Pentium Pro) is about 1/3 the speed of the fastest microprocessor (DEC Alpha or R10000).

- Fast ethernet (cards are now around $80)

`Loki`

Disabling Technologies

- Spending more than 10 minutes per week talking to "customer support." Giant corporations are making you beta test their broken software.

- Anything advertised as "making parallel programming easy." I don't need it. Neither do the people who will waste their time wondering why it doesn't work as advertised. I would rather have attention focused on making the C and Fortran 77 compilers faster, or writing a user-space network driver.

- Anything proprietary. I know it will be broken when I try to use it, so the documentation and source code better be available so I can fix it.

- Shared Memory.

`Loki`

Benefits

- Commodity components are inexpensive, easy to obtain, easy to maintain, easy to upgrade, and come with good warranties.

- A computer you build yourself to suit your problems can span a much wider range in architecture options.

- A computer that is under your total control can solve your problems in a manner which you choose. If it breaks, you know how to fix it. If it doesn't need to be upgraded with the latest software, you don't have to grit you teeth when "preventive maintenance" happens at just the wrong time.

Loki

Empowering the Power User

We are from the Computer Science Department, and we're here to help you...

- It is much easier to make a system work well for a single problem, than to be all things to all people. The greatest advantage I have is a problem that I need to solve. All advances are measured with respect to how they help to solve that problem.

- I believe that people who have a desire to understand the whole of a computer system will always achieve better results than those who wish to remain ignorant of the details.

- The people who write software that actually solve problems in the real world must strive to be self-sufficent. Those who write software dealing with computer-science issues seem to always be solving the wrong problems.

Hardware

- Nothing can beat Fast Ethernet for price/performance at the moment

- DEC 21140 (Tulip) Fast Ethernet cards are excellent performers

- You want as much memory bandwidth as possible

- You can never have too much memory. It's cheap as dirt, anyway.

- SMP is a terrible idea

Loki

Why SMP is a terrible idea

- We're already short on memory bandwidth and network bandwidth. Multiple CPUs make the problems even worse.

- If you are going to write a message-passing program, why do you want to have to deal with shared memory on top of that?

- Multiple processors sharing memory makes it a lot harder to write a stable and efficient operating system.

Loki

Reliability

- All Loki nodes were up for a two month period without a single minute of downtime. There have been 0 unexpected node crashes. There have been 0 pieces of hardware replaced since the initial burn-in.

- During burn-in, 1 bad SIMM and 7 bad Quantum EIDE disks were replaced under warranty. We have found that compiling gcc with itself is a very good memory and cache tester.

- During the round-trip from Los Alamos to Pittsburgh for Supercomputing '97, the only hardware problems encountered were 1 bad ethernet cable on the way out, and 3 bad ethernet cables after we came back. I attibute this to my poor wire-crimping skills (although 4 out of 160 cables isn't bad).

`Loki`

Software

The following pieces of software are critical. They must never fail. They are more important than any other components of the system.

1. The operating system.
2. The compiler.

The following pieces of software are very important.

1. The message passing library.
2. The debugger.
3. The profiling and performance monitoring system.

Loki

Message bandwith

- Multiple fast ethernet ports saturate at 20 Mbytes/sec overall. Our hardware (5 ports) should be capbable of 50 Mbytes/sec overall.

- The reason appears to be that memory bandwidth limits message bandwidth through the kernel to about 20 Mbytes/sec due to copies to user space.

- Hacked UNet without user space copy shows bus is capable of 40 Mbytes/sec, at least.

- Doing user space messages while avoiding the receive copy is tricky and will require some excellent software.

Loki

The MPMY Interface

These functions are the only ones which are fundamentally required for message passing programming. Our treecode uses the following interface on top of whatever works best (MPI, PVM, TCP sockets, UDP sockets, shared memory, NX, CMMD, EUI)

- void Init(int *argcp, char *** argvp);

- int Isend(const void *buf, int cnt, int dest, int tag, Comm_request *reqp);

- int Irecv(void *buf, int cnt, int src, int tag, Comm_request *reqp);

- int Test(Comm_request req, int *flag, Status *stat);

- int Nproc(void);

- int Procnum(void);

Loki

Debugging

- I am sick and tired of what Cray, Intel and others pass off as parallel debuggers. They are practically useless. I am forced to wonder how they manage to do any parallel code development themselves without a usable debugger.

- gdb "attach" works very well to determine the state of a single process.

- Tracing program flow and correlating events on different processors requires a vast amount of precise information which is not readily displayed in a graphical debugging tool. We use a library called "Msgs", which is basically what you end up with when you force "printf" to be a debugging tool.

```
Loki
```

Msgs

Msgs provide a primitive message logging facility. Messages can be turned on for particular files or on particular processors.

```
#include "Msgs.h"

Msg_turnon("main.c:0-3");

Msg_do("Data read, nobj=%d, gnobj=%d\n", nobj, gnobj);

Msgf(("%d interactions, pos=%g %g %g\n",
                       end-pp, ppos0, ppos1, ppos2));
```

Loki

A 200 Mhz Pentium Pro is capable of 200 Mflops doing adds or balanced adds and multiples, but only 100 Mflops doing purely multiplies.

Operation	Throughput (clocks)	Latency (clocks)
add	1	3
mul	2	5
div	8	8
sqrt	9	9
sin	84	84

Table 15: Floating Point Performance

Loki

Optimization Hints

- Don't waste your time looking for 10% improvements. Make sure that you aren't losing factors of two.

- Double precision floating point quantities should always be 8-byte aligned. This can make more than a factor of two difference. Use -malign-double with gcc and g77 to assure this. You also need an up-to-date Linux libc (5.4.23 or newer) to guarantee the stack pointer is initially 8-byte aligned.

- Unrolling is useless, unless you also eliminate dependencies which cause adder or multiplier pipeline stalls.

Loki

Unrolling to Eliminate Stalls

```
for (i = 0; i < n; i += 3) {
    sum += x[i];      /* This doesn't help */
    sum += x[i+1];    /* The adder stalls waiting for */
    sum += x[i+2];    /* the result to arrive in sum */
}
return sum;

for (i = 0; i < n; i += 3) {
    s0 += x[i];       /* This is the right way */
    s1 += x[i+1];
    s2 += x[i+2];
}
return s0+s1+s2;
```

Hardware Performance Monitoring and Profiling

Linux Performance Monitoring

Linux also maintains a great deal of relevant performance information in the /proc filesystem. (CPU, memory used, swap used, network utilization)

An array of xosview windows is a cheap and easy way to get good idea of the machine state across multiple nodes.

Loki

Things to Remember

- Loki is a real scientific computing resource, built by physicists to solve actual physics problems.

- Loki has superior price/performance for the majority of message-passing scientific application codes compared to all current commercial machines.

- In current systems, memory bandwidth is the single most important factor which limits scientific application performance.

- Solving an application problem is the final arbiter of success.

Loki
